ABSTRACT

The current study sought to evaluate the SASTSc in two samples of students taking a statistics course that incorporates statistical software. The SASTSc was given at two time points, once at the beginning of the semester and then again at the end of the semester. Our evaluation included examining competing factor analytic models, examining convergent validity, test-retest reliability, and assessing internal consistency. Our results in both samples replicate the scale's proposed factor structure; however, not all items were useful and we propose some changes to the wording of items to improve the scale. Data, analysis scripts, and results are made publicly available at https://osf.io/rv64m/?view_only=6dfbf883f0d841b69c238773cee6e62e.

Keywords: *statistics attitudes; assessment; scale development; attitudes toward statistical technology; statistical software*

1. INTRODUCTION

1.1. ATTITUDES TOWARD STATISTICS AND SOFTWARE

Attitudes toward statistics have received a fair amount of research attention (Bond et al., 2012; Griffith et al., 2012; Ramirez et al., 2012; Walker & Brakke, 2017). The majority of this research has focused on how attitudes are related to students' course performance (Dempster & McCorry, 2009; Emmioğlu & Capa-Aydin, 2012; Gal & Ginsburg, 1994; Lavidas et al., 2020) or statistics anxiety (Onwuegbuzie, 2004; Onwuegbuzie & Wilson, 2003). Substantially less research has focused on how attitudes toward statistics relate to software usage or examined attitudes toward using technology in statistics courses. The use of statistical software and technology in statistics courses is an important topic because it is becoming more intrinsically tied to statistics courses (e.g., Davidson et al., 2019). In fact, statistical software has become a necessary skill for applied statistics and data analysis. The Guidelines for Assessment and Instruction in Statistics Education (GAISE) put forth by the American Statistical Association (GAISE College Report ASA Revision Committee, 2016) noted that the biggest change with statistics education over the past several decades was the increased prevalence of statistical software. Further, Hernández (2006) argues that

software should be incorporated into statistics courses for social science students so that they gain a practical skill and avoid complex and sometimes anxiety-provoking mathematical computations.

Using statistical software in courses has become increasingly common in psychology undergraduate courses (Davidson et al., 2019), but few studies have examined students' attitudes toward statistical software nor the impact of statistical software on students' course performance, learning, or general statistics attitudes. One study investigated using the point-and-click software SPSS and found mixed results about its effect on grades and students' attitudes toward statistics in an undergraduate psychology statistics course in an Indonesian university (Jatnika, 2015). Specifically, the author found that after using SPSS for the duration of the course, students felt that their knowledge and skills in statistics were higher, but their course grades actually decreased compared to previous statistics courses. Brezavšek, Šparl, and Žnidaršič (2016) examined the use of SPSS in undergraduate introductory psychology statistics courses at a Slovenian university. They sought to examine the main factors influencing SPSS attitudes and later adoption of the software in a large structural equation model based on an extension of the Technology Acceptance Model (Davis, 1989). Both of these studies sought to determine the extent to which building competence with and positive attitudes toward statistical software can improve statistical attitudes. Recently, Counsell and Cribbie (2020) examined attitudes toward statistics and statistical software and course performance in students taking a psychology statistics course that uses the software R. They found that students with more positive attitudes toward R held more positive general statistics attitudes and had higher grades than students with relatively more negative attitudes. One limitation of these papers is that software attitudes were defined slightly differently because of the software used and the lack of validated measures of statistics software attitudes.

1.2. STUDENTS' ATTITUDES TOWARD STATISTICS AND TECHNOLOGY SCALE (SASTSC)

Anastasiadou (2011) created a measure for assessing attitudes toward statistics using technology called the Students' Attitudes toward Statistics and Technology Scale (SASTSc). Similar to the popular Survey on Attitudes toward Statistics (SATS) by Schau and colleagues (2003; 1995), the SASTSc measures several different domains for attitudes toward statistics, but it also includes technology- and software-specific items. Specifically, the measure includes five separate subscales, as follows: a) Statistics Cognitive Competence: positive and negative attitudes concerning a student's knowledge and skills as applied to statistics; b) Technology Cognitive Competence: positive and negative attitudes concerning a student's knowledge and skills as applied to technology; c) Attitudes toward Learning Statistics with Technology: positive and negative attitudes concerning a student's attitudes to learning statistics with technology; d) Value: positive and negative attitudes to the worth and usefulness of statistics in students' personal and professional life; and e) Affect: positive and negative emotions concerning statistics. Anastasiadou (2011) created the five subscales as a result of a principal components analysis (PCA) using an orthogonal, varimax rotation and found that coefficient α for the scale was .824.

An independent psychometric validation of the SASTSc by Anastasiadou (2011) is important for a number of reasons. First, the author used PCA instead of exploratory factor analysis (EFA). PCA is not recommended as a method for validating latent variables; it assumes no measurement error and simply breaks down the sample correlation matrix into a linear combination of components – not factors that mathematically comprise the

particular correlation structure seen in the sample. While PCA results may coincide with EFA results, the analyses have different purposes and are mistakenly used interchangeably (Costello & Osborne, 2005; Preacher & MacCallum, 2003). Second, Anastasiadou notes that a total score is not appropriate because the different subscales comprise unique attitudinal domains, so using coefficient α as a measure of internal consistency for the entire measure is not appropriate. A number of influential researchers have argued that coefficient α is over-used, not measuring what people think it's measuring, and not a very good measure of a scale's reliability because of its strict assumptions (Flora, 2020; McNeish, 2018; Sijtsma, 2009; Yang & Green, 2011). At the time of writing this manuscript, the SASTSc had been cited just over 100 times but the only external psychometric validation project translated the SASTSc into Persian for use with medical students in Iran (Saki et al., 2016). They found satisfactory reliability across the five subscales (α ranged from .78 to .88), but their confirmatory factor analysis (CFA) provided somewhat mixed results. Saki et al. (2016) argue that their model fit is good but their reported statistics (NNFI, CFI, RMSEA) do not meet recommended cut-offs (e.g., Hu & Bentler, 1999). Given the language differences, relatively small sample for a CFA ($N = 192$), and issues described above, more work establishing the SASTSc's measurement properties is crucial for researchers seeking to examine its five constructs.

1.3. STUDY AIMS

The current study seeks to validate the SASTSc in two samples of students currently enrolled in a statistics course that incorporates statistical software. Specifically, we will re-examine the scale's factor structure in Sample 1 using an EFA instead of a PCA, and then we will use a CFA in Sample 2 to validate the results obtained in Sample 1. In both samples, we will seek to uncover reliability evidence through coefficients α and omega (ω) and test-retest reliability. We will also test for convergent validity by examining the correlations of the SASTSc domains with the SATS domains.

2. METHOD

2.1. PARTICIPANTS

In total, we had 1060 participants from three academic institutions (two large urban Canadian universities in the same city and one medium sized STEM focused university in the United States). Of the total participants, 132 were immediately excluded from the total sample size for one of the following reasons: they were not taking a statistics course, their course was not using software, they did not consent to participate, already participated in the study in a previous semester, dropped out after completing less than 40% of the survey, or explicitly stated that their data should not be used in the analyses. Students were sampled from both undergraduate and graduate level courses in Psychology, Sociology, Kinesiology, and Business across three academic semesters (spanning 18 months). Data from the university in the United States was used in the exploratory factor analysis (EFA) while the two Canadian universities were pooled into one sample for use in a confirmatory factor analysis (CFA). Data for this study came from two separate projects; specifically, 244 participants came from Counsell and Cribbie (2020) and 816 participants came from Counsell et al. (2020).

EFA Sample. Sample 1 included 411 participants from 22 unique courses. All participants were currently enrolled in the same Analytics Masters program but varied considerably in their undergraduate degrees and statistics experiences. Of the total

participants, 171 (41.61%) had data at both time points, whereas 81 (19.71%) had time 1 data only and 159 (38.69%) had data at time 2 only. The majority of participants identified as East or South Asian (43.0% and 45.8% respectively). Just over 3% identified as White, 3.5% as Black, with the remaining racial categories accounting for about 1% each (Latinx, Middle Eastern, Mixed or Other racial identity). The median age in the sample was 28 years ($M = 28.44$, $SD = 3.35$). Of the 400 participants with gender identity data, 52.5% identified as female, 46.50% as male, and 1.00% as nonbinary or gender non-conforming. All participants used R as the primary software in their course.

CFA Sample. Sample 2 included 517 participants from 33 unique courses. Of the total participants, 164 (31.72%) had data at both time points, whereas 200 (38.68%) had time 1 data only and 153 (29.59%) had data at time 2 only. The Counsell and Cribbie (2020) survey did not include racial or ethnic identity as a demographic variable resulting in 47% missing data on this variable for Sample 2. For the remaining participants ($n = 227$), their ethnic/racial identity was reported as: 59.0% White, 4.8% Black, 3.5% Latinx, 12.77% East Asian, 5.7% South Asian, 7.9% Middle Eastern, 2.2% Indigenous, and 4.0% with a mixed or other ethnic identity. The median age in the sample was 21 years ($M = 22.32$, $SD = 4.57$). Of the 411 participants with gender data, 77.86% identified as female, 20.92% as male, and 1.22% as nonbinary or gender non-conforming. The majority of participants reported using R in their course (57.80%); however, 31.60% used SPSS, 6.36% used Excel, and 4.24% used another software (e.g., SAS, MATLAB).

2.2. PROCEDURE

Participants in Counsell and Cribbie (2020) filled out a short 10-minute paper and pencil survey during class time at two points in the semester: the first day of class and the last day of class. See their paper for the full procedure details. For the EFA data and remaining CFA data (Counsell et al., 2020), participants completed the survey online. Instructors of students eligible to participate mentioned the study in class and provided the survey link in the location where course files are housed. Instructors were provided with a script stating that they were not involved in the study and that participation was anonymous. A link to the online survey was posted twice: once at the beginning of their statistics course (for completion within the first two weeks of starting) and once again at the end of the term (within the last two weeks of their course finishing). The online survey included quantitative measures as well as qualitative questions whereby participants were able to provide further information about their experiences with learning statistical software in their course (at time 2 only).

Ethics approval was obtained from all three institutional Research Ethics Boards and student participation was voluntary. Responses to the survey questions were anonymous. To link a participant's surveys across the two time points, unique numeric ID variables were generated based on answers to a series of non-identifying questions (e.g., name of first pet, number of siblings, birth month). Optional email addresses were collected in a separate survey for incentives. Students in Sample 1 were awarded partial course credit for participation. Participants in Sample 2 were entered into a draw to win one of six \$150 gift cards (two per semester).

2.3. MEASURES

Students' Attitudes toward Statistics and Technology Scale (SASTSc). The SASTSc (Anastasiadou, 2011) is a 28-item scale measuring attitudes toward statistics and statistics technology. As described in the introduction, the scale includes five domains: i)

Statistics Cognitive Competence; ii) Technology Cognitive Competence; iii) Attitudes toward Learning Statistics with Technology; iv) Value; and v) Affect. Each of the items is measured with a Likert scale ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). Items are averaged into a composite score for each subscale, whereby higher scores are more positive. An example question from subscale iii) is “I prefer to use statistical software to evaluate statistical problems.” Although their original questions assessing technology asked about SPSS specifically, our items were adapted for broader applicability to students substituting the word “statistical software” for SPSS. The items used in the current study are available in the Appendix.

The original author reported satisfactory reliability scores for the five domains (α ranging from .74 to .90) in their Greek sample, and Saki et al. (2016) reported similar reliability scores using their Persian translated version. However, the factor structure of the English language SASTSc has not been validated through confirmatory factor analysis and the measure generally has little research investigating its measurement properties (Nolan et al., 2012).

Survey on Attitudes toward Statistics (SATS). To assess the SASTSc’s convergent validity with related scales, we also include the SATS (Schau, 2003). It is a 36-item scale with Likert type items assessing attitudes toward statistics among students currently taking a statistics course. The original 28-item scale (Schau et al., 1995) measured attitudes across four domains, whereas the revised revision includes six domains. Although correlated with one another, the subscales measure different domains and therefore a single total score for the scale is not appropriate. The subscales are i) Affect: feelings concerning statistics; ii) Cognitive Competence: perceptions of students’ own intellectual knowledge and skills in statistics; iii) Value: the value or worth attributed to statistics in students’ personal and professional lives; iv) Difficulty: the perceived difficulty of statistics; v) Interest: students’ level of individual interest in statistics; and vi) Effort: the amount of work students expend to learn statistics (Schau, 2003). Each item is rated on a 7-point scale expressing the amount with which the student agrees or disagrees with the item. Half of the items are negatively worded and must be reverse coded to compute subscale scores. An example of an item from the Affect subscale includes “I will like statistics” and an example of a negatively worded (i.e., reverse coded) item from the Cognitive Competence subscale is “I will have trouble understanding statistics because of how I think.” Higher scores on the subscales reflect a more positive attitude toward that domain with the exception of Difficulty, where higher scores reflect perceiving statistics as easier. The SATS does not have any items related to the use of statistical software.

The SATS has been found to have good convergent validity with other related scales, good internal consistency scores, and several research papers support the factor structure proposed [see Nolan, et al. (2012) for a review]. In our samples, we found sufficiently high internal consistency for ($\alpha > .80$) for the Affect, Cognitive Competence, Value, and Interest domains across both samples and time points. The Difficulty domain had values ranging from .59 to .76 by sample and time point. In Sample 1, the Effort subscale also had values $> .80$ but in Sample 2, α was .65 at Time 1 and .71 at Time 2.

3. RESULTS

3.1. SAMPLE 1

Data Quality and Missingness. Missing data were generally not a problem within each time point. Few participants were missing item level data which was treated as missing at random. At time 1 all items were missing less than 1.00% and at time 2 item

level missing data ranged from 0 to 1.88%. Accordingly, correlation matrices and factor analytic procedures were conducted using pairwise deletion.

We further examined the data for signs of inattention and random responding based on survey completion times, straightlining – i.e., selecting the same value for a large number of items in a row (Johnson, 2005), and extreme inter-item (within participant) response variability (Marjanovic et al., 2015). Data were considered of questionable quality if a participant completed the full survey in less than 600 seconds, scored greater than 2 *SD* above the mean for individual response variability or had a straightlining score of more than 10 items on the SATS or 20 items on the SASTSc. Note that the number is lower for the SATS because it has reverse coded items but the SASTSc does not. These measures resulted in flagging 68 participants at Time 1 as questionable and 92 participants at Time 2 as questionable. Twenty-seven of those participants had questionable data at both time points. We conducted a sensitivity analysis with the factor analysis to see whether including those with questionable data quality changed the results. Overall, the pattern of results did not drastically change; however, the results in the sample with questionable data produced EFAs with more cross-loadings, and generally, the correlations were stronger. We decided to present the results with the questionable data removed; however, the results from the full sample can be seen at https://osf.io/rv64m/?view_only=6dfbf883f0d841b69c238773cee6e62e.

Exploratory factor analyses. The EFA analyses were conducted at each time point using the *psych* package (Revelle, 2020) in R version 4.0.2 (R Core Team, 2020). For all analyses, the unweighted least squares (ULS) factor extraction method was used with an oblimin (i.e., oblique) rotation to allow for correlations between factors. Although items are ordinal (seven categories), reasonable variability and no drastic deviations from normality led to the decision to use regular Pearson correlations in the analyses. We examined scatterplots for obvious nonlinearity patterns and were satisfied that linear relationships adequately described the data. At Time 1, a parallel analysis (Horn, 1965) and the minimum average partial (MAP) test (Velicer, 1976) both suggested a 5-factor solution, while there were six eigenvalues greater than 1.00. At Time 2, the parallel analysis suggested four factors, and the MAP test and eigenvalues > 1.00 criteria suggested a 5-factor solution. We examined 4-, 5-, and 6-factor models at each time point, but, due to space constraints, we present only the 5-factor models for each time point because we believe that the 5-factor solution provides the best balance of interpretational and statistical evidence. All additional analyses, item level correlation matrices, and tables can be found at https://osf.io/rv64m/?view_only=6dfbf883f0d841b69c238773cee6e62e.

Time 1 EFA Results. Table 1 includes the factor loadings, communalities (proportion of variance in each item explained by their respective factor), and proportion of variance accounted for by each factor in the 5-factor solution. Across the five factors, there were minimal cross-loadings and the items loaded reasonably strongly onto the factor that matches the original structure reported in Anastasiadou (2011). Communalities were all greater than .40 with the exception of Item 18, which was only .15 and did not demonstrate sufficient loadings on any factor. The item, “Statistics makes me overqualified” appears to be a poorly worded item with a distribution that was almost uniform in nature. The five factors accounted for 65% of the variance in the items. Factor correlations are included in the lower diagonal of the correlation matrix in Table 2. The factors are all moderately correlated with one another with the exception of Technology Cognitive Competence and Value ($r = .10$). Of note is the strong correlation between Affect and statistical Cognitive Competence ($r = .57$), which will be elaborated further in the discussion section.

Table 1*Five Factor EFA Solution for Time 1 Data (N = 262)*

	Cog Comp	Affect	Stats Tech	Value	Tech Cog Comp	h^2
Item 1	.811	.089	.021	-.051	-.010	.720

Cog Comp	----	.61	.47	.33	.47
Affect	.57	----	.50	.49	.47
Stats Tech	.28	.43	----	.37	.50
Value	.33	.54	.36	----	.16
Tech Cog Comp	.43	.31	.42	.10	----

Notes: lower triangles include the factor correlations at Time 1, upper triangles include the factor correlations at Time 2. Cog Comp is the Statistical Cognitive Competence domain; Stats Tech is the Learning Statistics with Technology Attitudes domain, Tech Cog Comp is the Technological Cognitive Competence domain

Time 2 EFA Results. Table 3 includes the factor loadings, communalities, and proportion of variance accounted for by each factor in the 5-factor solution. Generally the results replicated the factor structure at Time 1 and the original structure reported in Anastasiadou (2011). Again, communalities were all greater than .40 with the exception of Item 18, which was only .09 and did not demonstrate sufficient loadings on any factor. This item was the same problematic item from the Time 1 EFA results. Although having a moderate communality, Item 17 did not demonstrate a reasonably sized loading on any single factor, but had a standardized loading around .20 on four of the five factors. Item 17 is “Statistics is valuable.” The five factors accounted for 66% of the variance in the items. Factor correlations are included in the upper diagonal of the correlation matrix in Table 2. Correlations at Time 2 were generally stronger than at Time 1 (especially between Cognitive Competence and Learning Statistics with Technology attitudes which increased from $r = .28$ to $r = .47$).

Reliability and convergent validity. Internal consistency reliability was examined using both coefficients α (Cronbach, 1951) and ω (McDonald, 1970, 1999). Test-retest reliability was calculated by correlating the Time 1 domain with its Time 2 counterpart. Reliability results can be found in Table 4. All subscales had α or $\omega > .80$ with most $> .90$ except for Value at Time 2 ($\alpha = .77$). All test-retest correlations were $> .60$ which we believe is indicative of reasonable test-retest reliability because attitudes toward statistics may shift somewhat over the duration of a statistics class. We further examined the correlations of the SASTSc subscales with the SATS subscales within each time point to test for convergent validity (see Table 5). All correlations of comparable subscales (e.g., Value on SATS and Value on SASTSc) were in the expected directions and moderate to large in magnitude.

Table 3*Five Factor EFA Solution for Time 2 Data (N = 160)*

	Cog Comp	Affect	Stats Tech	Value	Tech Cog Comp	h^2

3.2. SAMPLE 2

Data Quality and Missingness. As described above, missing data were also not a problem within a time point in the CFA sample. In the Time 1 data, item level missingness ranged from 2.09% to 2.99%. At Time 2, each item was missing between .34% to 1.37%). Missing data were treated as missing at random. We used pairwise deletion in the correlation analyses and full information maximum likelihood in the CFAs.

The same techniques for data quality described above were used in the CFA sample. Namely, data were examined for signs of inattention and random responding based on survey completion times, straightlining, and extreme inter-item response variability. Data were considered of questionable quality if a participant completed the survey in less than 600 seconds, scored greater than 2 *SD* above the mean for individual response variability or had a straightlining score of more than 10 items on the SATS or 20 items on the SASTSc. These measures flagged 29 participants at Time 1 as questionable and 26 participants at Time 2 as questionable. Only 1 participant had questionable data at both time points.

Notes: lower triangles include the correlations at Time 1 ($N=262$), upper triangles include the correlations at Time 2 ($N = 160$). SATS = Survey of Attitudes toward Statistics (Schau, 2003); SASTSc = Students Attitudes toward Statistics and Technology Scale (Anastasiadou, 2011); CogComp is the Statistical Cognitive Competence domain; StatsTech is the Learning Statistics with Technology Attitudes domain, TechComp is the Technological Cognitive Competence domain

We conducted a sensitivity analysis with the CFA models to see whether including those with questionable data quality changed the results. For consistency with the approaches taken in the EFA section, we decided to remove the poor-quality data. We examined scatterplots for obvious nonlinearity patterns and were satisfied that linear relationships adequately described the data and examined histograms for each item, which were approximately normal. We examined multivariate normality with Mardia's test (Mardia, 1970), which was violated. Accordingly, we employed a robust maximum likelihood estimator to correct for multivariate kurtosis.

Confirmatory Factor Analysis. We sought to replicate the results from the EFA and previous sample. Within each time point, we tested the five-factor model proposed in Anastasiadou (2011) as well as a five-factor model removing Items 17 and 18 from the Value factor. CFA models were conducted with the *lavaan* package version 0.6-6 (Rosseel, 2012) using maximum likelihood estimation with robust standard errors ('MLR' estimator) and full information maximum likelihood to handle the small amounts of missing data within each time point. Model fit was considered satisfactory if the CFI > .95, RMSEA < .08, and SRMR < .08 (Hu & Bentler, 1999; MacCallum et al., 1996). Due to space constraints, only standardized factor loadings and factor correlations are presented on the path diagram. However, full results can be obtained using the data and analysis scripts at https://osf.io/rv64m/?view_only=6dfbf883f0d841b69c238773cee6e62e.

Time 1 CFA Results. Model 1 includes the five-factor model described in Anastasiadou (2011) with no cross-loadings or residual covariances. This model demonstrated sub-optimal global fit statistics, $\chi^2(340) = 922.31, p < .001$ (Satorra-Bentler scaling factor = 1.14), CFI = .903, RMSEA = .077, 90% CI = [.071, .083], SRMR = .079. Model 2 followed the same structure as Model 1 but removed Items 17 and 18. Removing these two items slightly improved global model fit, $\chi^2(289) = 732.02, p < .001$ (Satorra-Bentler scaling factor = 1.13), CFI = .924, RMSEA = .073, 90% CI = [.066, .079], SRMR = .067; however, the CFI remained below the recommended cut-off. Next, we examined local misfit of each model based on the standardized residual matrix. In the first model, items 17 and 18 demonstrated high z-score residuals (> 3.00) with many of the other items, supporting their removal in Model 2. We also found that item 28 ("I am not afraid of statistics") had high residuals with eight other items. Despite being part of the Affect subscale, the item appears to tap more into statistics anxiety (see Chew & Dillon, 2014), which is not captured by any of the domains. Item 19 ("Statistics is a part of our daily life") also demonstrated some high residual covariances with a few of the items but was not as problematic as Item 28. Accordingly, we decided to re-specify the model after removing Item 28 (Model 3). Model 3 demonstrated good model fit, $\chi^2(265) = 587.49, p < .001$ (Satorra-Bentler scaling factor = 1.13), CFI = .942, RMSEA = .065, 90% CI = [.058, .072], SRMR = .061. Although the CFI is just under the .95 cut-off, we believe that this model fits sufficiently well and do not want to arbitrarily add cross-loadings or error covariances to improve model fit past the cut-off because these modifications are less likely to generalize (i.e., may be sample specific). The path diagram for our final model (Model 3) with standardized factor loadings and factor correlations is presented in Figure 1. The factor loadings are all strong (> .60) with most in the .80s range. The communalities ranged from .37 (item 26) to .94 (item 24). Factor correlations ranged from .25 (Value and Technology Cognitive Competence) to .75 (Affect and Cognitive Competence), with most falling in the medium to large range (.3 to .6). These results generally support the factor structure obtained in Sample 1 and the original author's validation (Anastasiadou, 2011), despite some problematic items.

Time 2 CFA Results. The same models from Time 1 were fitted to the Time 2 data. The pattern of global fit results for the same three models examined above was almost identical to their Time 1 counterpart. Namely, Model 1: $\chi^2(340) = 947.60$, $p < .001$ (Satorra-Bentler scaling factor = 1.14), CFI = .898, RMSEA = .084, 90% CI = [.077, .090], SRMR = .092; Model 2: $\chi^2(289) = 746.24$, $p < .001$ (Satorra-Bentler scaling factor = 1.16), CFI = .919, RMSEA = .079, 90% CI = [.072, .086], SRMR = .078; Model 3: $\chi^2(265) = 601.90$, $p < .001$ (Satorra-Bentler scaling factor = 1.17), CFI = .937, RMSEA = .071, 90% CI = [.064, .079], SRMR = .069. The strength of the loadings and magnitude of communalities was also comparable to what was observed in the Time 1 CFA models. Item 26 demonstrated the weakest relationship with its factor (Affect); it had a factor loading of .57 and communality of .32. All of the remaining factor loadings were $> .60$ with most in the .80s range and all communalities were $> .45$. The factor correlations were all $> .3$, ranging from .30 (Value and Technology Cognitive Competence) to .69 (Affect and Cognitive Competence). The same factor correlation pattern was observed as in Time 1 but the correlations on average were slightly stronger. We do not present the path diagram for this model again to avoid redundancy but the full details are available at https://osf.io/rv64m/?view_only=6dfbf883f0d841b69c238773cee6e62e.

Figure 1

Final Time 1 CFA Model with Standardized Factor Loadings and Correlations (N = 335)

Reliability and convergent validity. We used the same methods for examining reliability and convergent validity in Sample 2 as used in Sample 1. Reliability results for both time points can be found in Table 4. All subscales had α or $\omega > .85$ with most $> .90$, except for Value at ($\alpha = .75$ at Time 1 and $\alpha = .77$ at Time 2). Test-retest correlations were $> .50$ except for Cognitive Competence ($r = .47$). These correlations were a bit lower on average, compared to Sample 1. That said, we still believe the magnitude is indicative of adequate levels of test-retest reliability because attitudes may shift somewhat over the course of taking a statistics class. We further examined the correlations of the SASTSc

subscales with the SATS subscales within each time point to test for convergent validity. All correlations of comparable subscales (e.g., Value on SATS and Value on SASTSc) were in the expected directions and moderate to large in magnitude. Of note is that the correlational pattern was somewhat different from Sample 1. Notable differences on the SASTSc subscales include: Cognitive Competence and Affect were more strongly related in Sample 2, especially at Time 1; Affect and Value were more strongly related in Sample 1 at Time 1 only; and Value and Learning Statistics with Technology were more strongly related in Sample 1 at Time 1 only. See Table 6 for the Sample 2 SATS and SASTSc correlations.

4. DISCUSSION AND CONCLUSION

The current study sought to examine the psychometric properties of the Students' Attitudes toward Statistics and Technology Scale (SASTSc). We found that the factor structure mostly replicated the Anastasiadou's (2011) results (i.e., a five factor structure with the same items loading on the same factors), but there are some problematic items that warrant revision or removal. In both samples, Item 18 ("Statistics makes me overqualified") was problematic (low factor loadings and communalities). This item lacks specificity, is difficult to interpret, and with the importance of statistics skills for a variety of jobs, it is unlikely that statistical skills would make one overqualified for most positions that students would consider post-degree. Further, in Anastasiadou's (2011) paper, it was not clear whether the original scale was administered in Greek or in English (the sample consisted of Greek students). Issues with this item, therefore, may arise due to differences in translation or between native and non-native English speakers. A potential revision to the item that is more consistent with the other Value items is "Statistics skills make me more qualified for jobs." Item 17 also produced issues in the factor analytic solutions (at Time 2) with low loadings and communalities. This item ("Statistics is valuable") may be too broad. It is not clear whether the item is asking about the value of statistics for the student or whether generally speaking statistics is valuable. One potential revision could be "Statistics skills are valuable for me." Items 19 and 28 demonstrated sufficiently high loadings and communalities but were also somewhat problematic in that they had higher cross-loadings in the EFA or high residual correlations with other items in the CFA. We recommend removing Item 28 ("I am not afraid of statistics") because the item appears to tap more into statistics anxiety than statistics affect. As discussed in both Chew and Dillon (2014) and Nasser (2004), much of the attitudes literature fails to distinguish between statistics 'attitudes' and 'anxiety' and may use the terms interchangeably. Lastly, we recommend revising Item 19 ("Statistics is a part of our daily life") to "Statistics is relevant to my daily life" to tap into the participant's view of statistics as relevant to themselves rather than a broad and uncertain population (i.e., "our" daily life). All of these proposed changes are summarized in the Appendix.

Table 6*Convergent Validity: Pearson Correlations Between the SATS and SASTSc Domains in Sample 2*

	1	2	3	4	5	6	7	8	9	10	11

11. SASTSc Affect	.78	.68	.56	.50	.72	.06	.78	.54	.46	.49	----
T1 <i>M (SD)</i>	3.84 (1.24)	4.68 (1.14)	5.09 (1.04)	3.26 (.75)	5.00 (1.35)	6.60 (.55)	4.09 (1.32)	4.21 (1.30)	4.77 (1.20)	4.78 (.93)	4.11 (1.37)
T2 <i>M (SD)</i>	4.13 (1.36)	4.96 (1.12)	5.21 (1.19)	3.41 (.88)	4.97 (1.49)	6.24 (.82)	4.59 (1.29)	4.51 (1.38)	4.98 (1.43)	4.96 (1.02)	4.67 (1.37)

Notes: lower triangles include the correlations at Time 1 ($N=327$ with pairwise deletion), upper triangles include the correlations at Time 2 ($N=290$ with pairwise deletion). SATS = Survey of Attitudes toward Statistics (Schau, 2003); SASTSc = Students Attitudes toward Statistics and Technology Scale (Anastasiadou, 2011); CogComp is the Statistical Cognitive Competence domain; StatsTech is the Learning Statistics with Technology Attitudes domain, TechComp is the Technological Cognitive Competence domain

Our data further demonstrated good internal consistency for the five domains of the SASTSc and convergent validity with the domains in the SATS. Of note is that the Value domain had the lowest reliability scores. The problematic items 17, 18, and 19 are all part of this domain. Although the α and ω scores are considered adequate support of internal consistency, improving the specificity of the items would likely improve these scores since the content of the revised items should be more consistent with the other items on the same domain. The remaining domains had scores in the .80s or .90s range providing strong evidence for the consistency of items on similar domains. Correlations between the SASTSc domains and relevant SATS domains were generally strong in magnitude (e.g., $r = .48$ to $.67$) supporting the convergent validity of the SASTSc domains. The SASTSc Value domain, though had generally lower correlations with the other domains (e.g., only $r = .43$ with the SATS Value domain) and small to medium correlations with other domains, providing further support for the necessity of revising some of the items on this subscale.

Despite the psychometric evidence in favour of using the SASTSc, there remain some additional topics that warrant discussion. Anastasiadou (2011) discusses how the measure can be used as pre-post assessment for statistics courses, but our results found a few differences in correlational patterns at the beginning vs. end of a statistics course. At the end of the course, Item 17 had moderate cross loadings across the domains instead of one prominent one on Value. The broadness of the original item may have appealed to students before they had a lot of experiences with statistics and software (i.e., at Time 1), but produced more ambiguity at Time 2 where they may be thinking about whether statistics is valuable to them personally, or on a societal level. Since Value and Affect are moderately correlated, their own feelings toward statistics course also be intertwined with their value. We were somewhat surprised that there were not more psychometric differences across the time points, as attitudes have the potential to shift, but the relationships between the SASTSc and SATS domains were stronger or weaker depending on the time point and sample.

In fact, some of the domains were correlated so highly with one another that it introduced some skepticism into them being separate theoretical constructs. Specifically, the Affect and Cognitive Competence domains were highly related (e.g., correlations ranging from .57 to .75 across time points and samples). Because the higher correlations tended to occur at Time 1, this result supports previous research about how attitudes toward statistics are strongly tied to students' own perceptions of their statistical ability and their preconceived ideas about statistics before even taking their course (Bond et al., 2012; Dempster & McCorry, 2009; Evans, 2007). Correlations closer to .5 or .6 at Time 2 may suggest some attitudinal shifts after taking a statistics course. Lastly, we had some concerns about the wording or language of some of the items even though the factor analytic results were not problematic. The Technology Cognitive Competence subscale and Learning Statistics with Technology subscale include terms like "technology" and "software" which may be interpreted differently by participants. It is not clear whether technology relates to topics such as cell phones, computers, tablets, applications, statistical software, and so on. Accordingly, it may be advantageous to increase the specificity of these items to clarify what technology means, perhaps changing "technology" to "statistical software" in Items 11-15 as is used in Item 16.

This psychometric validation contributes to the literature by providing support for the use of the SASTSc in evaluating attitudes toward statistics and technology in students currently taking a statistics course. Because research into attitudes toward statistics in courses using software is an understudied area compared to general statistics attitudes, researchers need to have scales that demonstrate appropriate psychometric properties to

measure these constructs. Statistical software and technology is one of the most useful aspects of statistics courses, particularly for students in mathematics adverse fields like the social sciences (Hernández, 2006). In fact, learning theory research (e.g., Eccles & Wigfield, 2002) stipulates that students learn and perform best in courses where they feel that the course material has value and that they are able to succeed. Accordingly, assessing how students build software competence and self-efficacy and their attitudes toward statistical software is another important step in predicting students' course performance and general attitudes toward statistics. Building positive experiences (including competence) with statistical software are also important for preparing students for the reality of data analysis in professional or graduate programs, or non-academic careers (industry, government, etc.).

With minor modification, instructors can easily incorporate the SASTSc into their courses to examine how attitudes toward statistics, technology and learning statistics with software change over the duration of a statistics course. Although the original author had items particular to SPSS, we have modified the items to apply more generally to statistical software but instructors could further adapt the “software” in the items to the specific software they use in their class (Excel, SPSS, R, SAS, etc.). The measure is brief enough that it only takes a couple of minutes to fill out all of the items, allowing for its use in the classroom as well. Further, many of the items could be adapted for populations that are not currently taking a statistics course. Given the issues described above for items 17, 18, and 19, we would recommend re-examining the factor structure again for the Value subscale in particular.

It is important to note the limitations of the current study. First, because we changed the items that referenced SPSS to reference ‘statistical software’ instead, our results are not perfectly comparable to those of Anastasiadou (2011). However, due to potential translational differences and the need for adapting the measure for software other than SPSS, we believe that the modifications were justifiable. Second, differences in psychometric properties of the test depending on the software used is possible. Although we do not discuss it in the paper, we did some exploratory analyses, separating Sample 2 into two sub-samples based on whether the software used was syntax based (e.g., R, SAS) or point-and-click (i.e., Excel, SPSS) and re-examined the five factor solution. The two subsamples demonstrated similar factor loading patterns, but the loadings in the point-and-click software group tended to be slightly lower, on average. Future studies should seek to examine potential differences further. Lastly, to obtain large enough samples for our EFA and CFA analyses, we did need to use samples from different classrooms and universities, which necessarily introduces heterogeneity into the sample without explicitly modeling the sources of that heterogeneity. The samples differed by ethnic and gender identity as well as by study major. Despite these differences, we were able to replicate the same factor structure pattern and reliability results, which speaks to the robustness of the findings.

ACKNOWLEDGEMENTS

The authors would like to acknowledge the financial support provided to the first author from the Social Sciences and Humanities Research Council (Insight Development Grant 2019-2021). We would also like to thank the course instructors from the three institutions for posting the study information to their students and Linda Farmus for her role in helping with data collection for the project.

Appendix

Students' Attitudes toward Statistics and Technology Items Used and Proposed Changes

Cognitive Competence

1. I am confident with statistics.
2. I can understand statistical reasoning easily.
3. I can understand statistical inference easily.
4. I can learn statistics easily.
5. I can solve difficult statistical test-hypothesis problems.
6. I get high marks in statistics.

Technology Cognitive Competence

7. I am very good with computers.
8. I don't have problems using software.
9. I can easily run statistical software.
10. I can fix problems that arise while using statistical software.

Learning Statistics with Technology

11. Technology makes the learning of statistics easier.
12. Technology makes the learning of statistics more interesting.
13. Technology helps me to understand statistics.
14. I prefer to use technology to evaluate statistical problems.
15. I like to use technology to make statistical graphs.
16. Statistical software helps me to discover many different statistical applications.

Value

17. Statistics is valuable. *
18. Statistics makes me overqualified.*
19. Statistics is a part of our daily life. *
20. Statistics helps me to understand our economy.
21. Statistics helps me to understand politics.
22. Statistics helps me to understand news reports.

Affect

23. Learning statistics is enjoyable.
24. I like learning statistics.
25. Statistics is interesting.
26. Statistics is not a frustrating discipline.
27. I find solving statistical problems satisfying.
28. I am not afraid of statistics. *

Proposed Changes to Starred Items

17. Statistics skills are valuable for me.
18. Statistics skills make me more qualified for jobs. [possibly remove item]
19. Statistics is relevant to my daily life.
28. Remove item
