Abstract

While the Holocaust is widely regarded by Germans as one of the worst human atrocities, they differ in their readiness to express guilt or, in contrast, in their demand to close this chapter of history. We propose that such demand for historical closure (HC) is particularly pronounced among individuals high in collective narcissism and is systematically related to reduced collective guilt. Across three studies ($N = 1383$), collective narcissism was significantly related to demand for HC, even when controlling for national identification and national pride. Moreover, collective narcissism was associated with reduced guilt only via demanding HC, but not via the defensive strategies generalization or moral delegitimization of the victims. Yet, collective narcissism was associated via all three defensive strategies with actual donations to support Holocaust survivors. We discuss how demanding HC helps group members to shield their ingroup from its negative past, thus alleviating aversive feelings of collective guilt.

Keywords: historical closure, collective narcissism, collective guilt, historical defensiveness, ingroup positivity

Too Great to be Guilty?

Individuals High in Collective Narcissism Demand Closure regarding the Past to Attenuate Collective Guilt

“A people that has achieved such remarkable economic success has the right not to have to hear anymore about Auschwitz.” Franz-Josef Strauss (1969)

“And this stupid policy of dealing with the past, it paralyzes us today much more than in Franz Josef Strauss' time. [...] We need a living culture of remembrance, which first and foremost brings us into contact with the great achievements of the ancestors.” Björn Höcke (2017)

Turned in ever new ways, German politicians have phrased the demand for a historical closure (HC) regarding the National Socialist past. Although there are almost 50 years between the quotes of former chancellor candidate Franz Josef Strauss (1969; as cited in Judt, 2005) and today's right-wing politician Björn Höcke (2017; as cited in Nowotny, 2017), the core message remains the same: It is time to draw a “*Schlussstrich*” (thick line) between contemporary Germany and Nazi Germany. A central motivation for these calls for a HC seems to be the desire to avoid collective guilt, i.e., a group-based emotion experienced when one's ingroup has illegitimately harmed another group (Doosje et al., 1998). Collective guilt is highly aversive and poses a major threat on the ingroup image (Branscombe et al., 1999). Therefore, particularly group members who identify strongly with their group tend to engage in a variety of strategies to avoid collective guilt (Branscombe & Miron, 2004; Wohl & Branscombe, 2008).

Demanding HC by denying the relevance to further engage with the past may serve as a particularly powerful strategy to reduce collective guilt. By claiming that the past is now

outdated, it becomes easier to morally disengage (Bandura, 1999), to distance the ingroup from the moral and practical implications of past harmful acts (Jeong & Vollhardt, 2020), or to question public representations of group history (i.e., historical charters; Hilton & Liu, 2017). In this paper, we argue that a form of defensive ingroup positivity, i.e., collective narcissism (Golec de Zavala et al., 2009), is connected to low collective guilt via demand for HC. We further argue and show that demanding HC is associated with collective narcissism in particular and not with all types of ingroup positivity. We also examine whether demanding HC mediates the association between collective narcissism and collective guilt, controlling additionally for two other defensive strategies as mediators: moral delegitimization of victims (Bandura, 1999; Opatow, 1990) and the demand for recognition of the perpetrator group's suffering (Noor et al., 2012; Wohl & Branscombe, 2008). We test these contentions across three studies within the context of Germans' willingness to accept collective guilt for the Holocaust.

Narcissistic Ingroup Positivity and Collective Guilt

According to the Social Identity Theory (Tajfel & Turner, 1986), a relevant part of people's sense of self is derived from the groups to which they perceive themselves as belonging. As such, group members are motivated to see their group in a positive light. The present-day social identity of groups is considerably influenced by historical events and their representation (Liu & Hilton, 2005). An instance of historical intergroup harm committed can pose a major threat to the group identity (Branscombe et al., 1999), and lead to aversive feelings of collective guilt (Doosje et al., 1998; Imhoff et al., 2013). Especially individuals who identify strongly with their ingroup (Klein et al., 2011) tend to downplay the relevance of such a past (thereby investing considerable mental resources, Sharvit et al., 2015) in order to protect their social identity and minimize feelings of group-based guilt. Empirical studies support the relationship between different types of ingroup identification (in the present article more broadly referred to as *ingroup positivity*) and reduced collective guilt in various historical contexts,

including Australia (McGarty et al., 2005), the Netherlands (Zebel et al., 2007), and Germany (Dresler-Hawke & Liu, 2006). Yet, a minimum level of group identification seems necessary to experience collective guilt (Klein et al., 2011).

We argue, like others (e.g., Marchlewska et al., 2020), that it is not ingroup positivity per se but rather an overly positive but fragile view of the ingroup that is related to defensive motivations. Expanding the concept of individual narcissism to the intergroup level, collective narcissism describes an emotional investment in an unrealistic belief about the ingroup's greatness, but one that is fragile and demands constant validation (Golec de Zavala et al., 2009). Hence, collective narcissism is associated with a strong need for constant affirmation of the overly positive ingroup image, coupled with a pronounced need to defend the ingroup against any criticism (Cichocka, 2016). In contrast to collective narcissism (i.e., narcissistic or defensive ingroup positivity),¹ non-narcissistic or secure ingroup positivity describes an unpretentious investment in the group which is independent of the praise by others and thus lacks the defensive motivation which is typical of collective narcissism (Golec de Zavala et al., 2013a). As such, secure ingroup positivity can be expressed in a confidently held positive perception of the ingroup, including an uninflated sense of ingroup identification or pride resulting from a realistic evaluation of the ingroup's strengths (Cichocka, 2016; Golec de Zavala et al., 2019). Accordingly, ingroup threats are expected to fuel defensive reactions particular in individuals high in collective narcissism but not in individuals with a non-narcissistic, secure ingroup positivity. It is important to note, that even relatively secure types of ingroup positivity (e.g., genuine ingroup identification or pride) may contain defensive components. Thus, the effects of secure (as opposed to narcissistic) ingroup positivity should be particularly apparent when controlling for shared variance with collective narcissism, thus capturing defensive components in rather secure measures of ingroup positivity (e.g., Marchlewska et al., 2020).

With respect to reactions toward a shameful past, prior research on individual narcissism suggests that narcissists, but not people with high genuine (or secure) self-esteem, tend to distance themselves from memories of a self-threatening past (Marchlewska & Cichocka, 2017). Specifically, individual narcissism (but not secure self-esteem) significantly predicted third-person perspective (i.e., a distancing strategy that helps to disentangle the past from the present self; Sutin & Robins, 2008) when recalling self-threatening (shameful) but not self-boosting situations. Although collective and individual narcissism operate on different levels (self-image vs. ingroup image) and individual narcissism is not necessarily accompanied by high scores in collective narcissism (Golec de Zavala et al., 2019), both concepts are marked by pronounced defensiveness to maintain a positive self- image (individual narcissism) or group-image (collective narcissism). Considering these functional similarities in defensive responses to threats (Cichocka, 2016), it seems plausible that while individual narcissism (but not secure self-esteem) may reinforce defensive reactions toward a shameful individual past, collective narcissism (but not secure ingroup positivity) may lead to defensive reactions toward a guilt-inducing group past. So far there has been little research that has brought together collective narcissism and collective guilt (e.g., Imhoff, 2010a). However, since the ingroup's involvement in historical harmdoing can pose a powerful threat to the positive group image (Branscombe et al., 1999), we argue that individuals high in collective narcissism should be particularly motivated to react defensively toward reminders of the ingroup's perpetrator past, thereby alleviating feelings of collective guilt.

Closing off the Past: The Demand to Draw a Line Under an Aversive Perpetrator Past

A crucial means by which group members can shield their ingroup image is by demanding HC - the call for drawing a final line under the perpetrator history and closing the book of history on that chapter (Imhoff, 2010b). Hanke et al. (2013), define HC as “an attitude toward the past and its relevance to the present and future” (p. 289). Specifically, demanding HC distances

today's group members from past ingroup transgressions by negating their continued relevance and the legitimacy to further engage with them. Thus, demanding HC is not merely a demand for silencing (Klar & Bilewicz, 2017) public discourse about the past. Rather, by claiming that the past is no longer relevant, HC removes the basis for the need for public discussions about the past. As such, claiming HC has been conceptualized as an *emotion-regulation strategy* (Bilewicz, 2016) that may help members of former perpetrator groups to downregulate the unpleasant feeling of collective guilt (Doosje et al., 1998). This perception of HC also resonates with the argumentation of several theorists (e.g., Adorno, 1955, 1963; Ahlheim & Heger, 2002; Rensmann, 1998, 2004) who have conceptualized demand for HC as a central expression of *defensiveness* against the aversive feeling of guilt resulting from past ingroup perpetration. The relationship between endorsing HC and reduced collective guilt can be explained by several different mechanisms. Examining the specific contributions of each mechanism is beyond the scope of the present study, but it is important to note that they make similar predictions.

Achieving HC may serve to subjectively push the past away. According to Wilson and Ross (2003), although time is chronological, construals of events can shift depending on whether that event subjectively *feels* close or far away in time from the current moment. Building on this, Peetz and colleagues (2010) showed that as the perceived distance between the present and past ingroup harmdoing increased, the acceptance of collective guilt decreased. Figueiredo et al. (2015) furthermore demonstrated that perceiving ingroup wrongdoings as temporally distant allowed individuals to downregulate ingroup-directed negative emotions and reduced the willingness to compensate the victims. Herein, we assess another way that time might be used to undermine collective guilt – through demanding HC. By closing off the past to the present, group members can still acknowledge the ingroup's responsibility for past wrongs, whilst shielding contemporary group members from collective guilt.

Besides allowing the perpetrator past to be shifted away in temporal space, HC can also serve to symbolically distance the ingroup from the past by denying the ongoing relevance of the misconduct committed and any continuing moral responsibility that might justify the experience of collective guilt. Zimmermann et al. (2011) differentiated between causal responsibility (i.e., acceptance that the ingroup has caused suffering) and moral responsibility (i.e., a sociomoral norm implying that the consequences of past transgressions are still important and need to be addressed). Particularly the latter type of responsibility might be challenged by demanding HC: If the past is considered irrelevant to the present (a core belief of HC), the foundation for the sociomoral norm to address this past in the present is withdrawn. Indeed, Zimmermann et al. (2011) found that the perceived relevance of a harmful past to the present has a substantial influence on the acceptance of the ingroup's moral responsibility. Moral responsibility, in turn, has been theorized to constitute a crucial predecessor of collective guilt (Wohl et al., 2006), and was empirically found to mediate the relationship between collective guilt and victim compensation (Zimmermann et al., 2011). Imhoff et al. (2013) further demonstrated that when the past was perceived as having little relevance to the present, acceptance of collective guilt was reduced. Thus, drawing a line under the history and denying its ongoing relevance for present times may shield the ingroup against its own negative past, thereby undermining collective guilt.

One of the contexts that can be perceived as particularly central to the analysis of historical defensiveness and collective guilt dynamics is Germany (Rensmann, 2004). In Germany, denying the continuing relevance to further deal with the atrocities of the Third Reich has been a topic for heated public debate (Brumlik et al., 2004). Although calls for closure on German Nazi past have met with strong political opposition and were supported almost exclusively by politicians within the right-wing spectrum (Sturm, 2019), population-representative surveys show that a stable proportion of German respondents agree with the statement that Germans "should no longer talk so much about the persecution of the Jews, but

finally draw a line under the past.” (60% in 1991, 58% in 2008, 55% in 2013; see Bertelsmann Foundation, 2015 p. 25). This agreement was particularly high among individuals with political preferences within the right-wing populist spectrum (80%; Hilmer, 2020). Since the collective narcissistic desire to maintain a positive ingroup image might be particularly prevalent within the right-wing populist spectrum (Golec de Zavala & Keenan, 2020), it might be collective narcissism that drives this popularity of HC. Overall, it thus seems relevant to test whether collective narcissism is substantially associated with enhanced demand for HC. We, however, know of little empirical research that has systematically examined the specific link between individual differences in collective narcissism and demanding HC as well as further downstream consequences for collective guilt and victim compensation.

Present Research

Across three studies, we addressed the relationship between collective narcissism, the German demand to cease discussing the Holocaust, and collective guilt. Study 1 was designed to establish the basic link between collective narcissism and collective guilt via demand for HC. In Study 2, we tested whether demanding HC would mediate the relationship between collective narcissism and guilt, even when controlling for two additional defensive mechanisms (moral delegitimization of the victims and calling for recognition of the perpetrator group’s suffering). Moreover, in line with previous research (e.g., Golec de Zavala et al., 2013a; 2013b), we sought to distinguish the unique effects of collective narcissism and rather secure types of ingroup positivity (genuine national identification and national pride) on demand for HC by accounting for their shared variance, and to manipulate the defensive reaction of collective narcissists by introducing ingroup praise (vs. criticism). Finally, Study 3 tested the mediation model with regard to an ecologically valid outcome, namely donations to a social initiative that supports Holocaust victims. Pre-registrations of Study 2 and 3, raw data, full R syntaxes and supplemental online materials (SOM) are available on our OSF project site accessible at <https://osf.io/d25zn/>.

A note on statistical “mediation”

Our theoretical reasoning rests on the notion that individual differences in collective narcissism reduce emotional experiences such as collective guilt via defensive mechanisms such as pushing the atrocities further back into the past. This is a unidirectional causal assumption that would make a clear prediction about statistical mediation. Statistical mediation is thus necessary but not sufficient in order for our theoretical consideration to be valid since it does not provide evidence for the assumed causal paths (Fiedler et al., 2011). We alert readers to this important caveat as the terminology of mediation (i.e., indirect or total “effects”), which we used for ease of comprehension, evokes a misunderstanding of implied causality. To be clear, our theoretical rationale implies mediation, an observed mediation does not imply the rationale was true.

Study 1

Study 1 was conducted as an initial test of the mediation model whereby demand for HC mediates the association between collective narcissism, and acceptance of collective guilt. We hypothesized that group members should be especially likely to demand HC on the ingroup-threatening perpetrator past to the extent that they are high in collective narcissism. In line with previous research on historical defensiveness strategies in regulating collective guilt (Castano & Giner-Sorolla, 2006; Imhoff et al., 2012; Swim & Miller, 1999), we also anticipated that a high demand for HC (i.e., an explication of defensiveness against a further confrontation with the perpetrator history) would be related to low levels of collective guilt.

Method***Participants***

A sample of 454 participants was recruited for an online survey on attitudes regarding German history. The study was advertised via online forums, a university mailing list, and websites providing links to participation in unpaid online surveys. Participants who were born outside Germany and raised in a family with recent migration background were excluded from

analyses. The final sample thus consisted of 384 German citizens (31% of participants identified as men, 69% as women) with a mean age of $M = 24.54$ years ($SD = 8.54$; age ranging from 15 to 80).

Procedure and Materials

Four items from the subscale on HC of the Secondary Antisemitism Scale by Imhoff (2010b) were used to measure the demand for closure regarding the Nazi era (e.g., “I am tired of hearing about the crimes against the Jews during the Holocaust over and over again”, $\alpha = .89$; $M = 3.47$, $SD = 1.77$). To assess the feeling of guilt in face of the German crimes against Jews ($\alpha = .89$), we used four items adapted from the Collective Guilt Acceptance Scale by Branscombe et al. (2004; e.g., “I feel guilty about the negative things the Germans did to the Jews in the past”; $M = 3.62$, $SD = 1.79$). Items on demand for HC and collective guilt were anchored at 1 (*strongly disagree*) and 7 (*strongly agree*). Finally, we included the nine-item Collective Narcissism Scale by Golec de Zavala and colleagues’ (2009; e.g., “Not many people seem to fully understand the importance of Germans”; $\alpha = .86$; $M = 2.17$, $SD = 0.83$). Scale anchors ranged from 1 (*strongly disagree*) to 6 (*strongly agree*).

Results

Collective narcissism was significantly correlated with demanding HC ($r = .52$, $p < .001$) and collective guilt ($r = -.19$, $p < .001$). Demanding HC and collective guilt were also intercorrelated ($r = -.34$, $p < .001$). In all studies of the present paper, mediation analyses were conducted by means of path analyses using the R package “lavaan” (Rosseel, 2012) and 95%-bootstrap confidence intervals were calculated using 5000 iterations as recommended by Preacher & Hayes, 2008. Results of a simple mediation analysis of collective narcissism on collective guilt via HC are reported in Table 1. In line with expectations, collective narcissism was related to claims for HC, which in turn were related to collective guilt. The indirect effect via demanding HC was also significant, while the direct path between collective narcissism and

collective guilt was not. Accompanied by a significant total effect, this pattern of results supported that the association between collective narcissism and collective guilt was fully mediated via HC. In other words, individuals high in collective narcissism demanded more HC and in turn reported less collective guilt. Additional control analyses indicated that this mediation model remained stable, even when controlling for age and gender (SOM A).

[Table 1 here]

Discussion

The results were compatible with our hypothesis that Germans high in collective narcissism want to close the door on the image-threatening perpetrator past, with downstream consequences for collective guilt. These findings are in line with the perception of demand for HC as a strategy of historical defensiveness (Bilewicz et al., 2016) and support the long-standing assumption that demanding HC can help to regulate aversive feelings of guilt (Adorno, 1955; Rensmann, 1998). By linking these defensiveness dynamics to collective narcissism, the study furthermore extends previous research on collective narcissism (Golec de Zavala et al., 2009, 2019) and provides evidence for the so far sparsely studied (Imhoff, 2010a) association of collective narcissism with collective emotions after historical transgressions.²

Study 2

We aimed at replicating the pattern of associations found in Study 1, thereby delimiting the specific effect of demand for HC in reducing collective guilt. Therefore, we additionally controlled for two other prominent defensive strategies: Moral delegitimization of the victims and demand for recognition of the perpetrator group's suffering (Bandura, 1999; Imhoff, 2010b; Noor et al., 2012; Opatow, 1990; Wohl & Branscombe, 2008). The former mirrors the allegation that Jewish people perpetuate the memory of the Holocaust for dishonest, self-serving motives (Imhoff, 2010b). As such, moral delegitimization can be seen as a strategy to question the legitimacy of the ongoing confrontation with Germany's perpetrator past by means of morally

disqualifying this confrontation. The demand for recognition of the perpetrator ingroup's suffering may, on the one hand, reflect the need for moral restoration of the perpetrators, since victim status tends to be associated with higher morality than perpetration (Noor et al., 2012). On the other hand, it may reflect the desire to relegate confrontation with the suffering of the victim group to the background in favour of addressing the suffering of the perpetrator group. From this point of view, both moral delegitimization and the call for recognition of perpetrator suffering could ultimately represent different justifications for the demand to finally close the chapter on Germany's Nazi past. Capturing the demand for HC could therefore reduce the association of moral delegitimization and the demand for recognition of perpetrator suffering with collective guilt. Against this backdrop, we hypothesized that collective narcissism would lead to more collective guilt, mediated by demand for HC, even when controlling for potential mediating effects of moral delegitimization of the victims and calling for recognition of the perpetrator group's suffering.

Additionally, we aimed at narrowing down the specific effect of collective narcissism relative to rather secure types of ingroup positivity. For this purpose, we controlled for national pride resulting from perceived strengths of the ingroup (Mussotter, 2018) and genuine national identification, reflecting the feeling of connectedness to one's ingroup (Sani et al., 2015).

Although national identification and pride also include a positive evaluation of the ingroup, they are not associated with a marked need for constant affirmation of the special significance of the ingroup, as is the case with collective narcissism (Cichocka, 2016). Based on the reasoning that it is narcissistic but not secure ingroup positivity which drives defensive responses (e.g., Marchlewska et al. 2020), we tested whether demanding HC would be positively associated only with collective narcissism when controlling for the shared variance with national identification and pride.

Finally, we aimed at modifying the extent of collective narcissistic defensive reactions. Prior research indicated that under ingroup praise (vs. criticism), the association between collective narcissism and defensive reactions was significantly reduced (Golec de Zavala et al., 2013b). In other words, praise seemed to buffer the extent of collective narcissistic defensiveness. Hence, we hypothesized that ingroup praise would function as a moderator, to the extent that individuals high in collective narcissism demand less HC when confronted with ingroup praise (vs. criticism). Since we expected this interaction effect to be specific to collective narcissism and not primarily driven by variance components that overlap with the other ingroup positivity measures, we hypothesized to find a significant interaction of condition and collective narcissism even when controlling for the two-way interactions of condition and national identification as well as national pride. For exploratory purposes, we included a neutral control group to see whether praise could be a buffer even in relation to a neutral condition.

Method

Participants

Golec de Zavala et al. (2013b) found a local effect size of Cohen's $f^2 = 0.03$ for the interaction effect of praise/criticism and collective narcissism on defensive intergroup hostility (see ΔR^2 for the two-way interaction in their Study 1; within their paper, in Study 1 the smallest ΔR^2 for two-way interactions of condition and collective narcissism was found). A power analysis in G*Power (Faul et al., 2017) indicated that 258 participants were required to achieve a power of 80% for this interaction effect. Since we also had a control group, we aimed to reach a total sample of $N = 380$. Due to a very fast online response rate, however, the survey was completed by 698 participants within the pre-registered time period for data collection. However, even when performing all analyses using only the first 380 participants, the results did not differ in statistical inferences from the present results.

The study was advertised as a study on attitudes toward German history via diverse social media forums and a university mailing list. In line with the pre-registered exclusion criteria, participants who indicated that they clicked randomly ($n = 14$), outliers of extremely fast termination (relative speed index > 2.0 ; Leiner, 2019; $n = 8$), Jewish participants ($n = 3$), as well as participants who speak any other language than German at home or participants who indicated that they were refugees ($n = 81$) were excluded from analyses. The final sample thus comprised 595 participants (61% of participants identified as women, 38% as men, and 1% as diverse individuals) with mean age of $M = 37.98$ years ($SD = 15.37$, age ranging from 18 to 88).

Procedure and Materials

We first assessed collective narcissism (same measure as that used in Study 1), genuine national identification (measured with four items by Sani et al. 2015; e.g., “I feel a sense of belonging to my country”), and national pride (captured with six items by Mussotter, 2018; e.g., “How proud are you of the social system in Germany?”). Subsequently, participants were randomly assigned to one of the three priming articles, followed by the manipulation checks. In the praise condition ($n = 205$), participants read an article that emphasized Germany’s exemplary way of dealing with the Nazi past. Perceived success in dealing with the perpetrator past might highlight the ingroup’s moral growth in the aftermath of former transgressions and was found to enhance perceived ingroup morality (Kazarovytska et al., 2022). Conversely, in the criticism condition ($n = 170$), Germany’s way of dealing with the past was introduced as deficient. A third group of participants ($n = 220$) was assigned to a neutral condition including an article about an indigenous people (see our OSF project site for full articles). Two items were used to check manipulation efficacy: “The opinion about Germany in the presented newspaper article was...”, and “What feelings did the article you read trigger in you?” (1 = *very negative* to 5 = *very positive*).

Next, participants were directed to measures of defensive mechanisms, captured by different subscales of Imhoff's (2010b) Secondary Antisemitism Scale. Demand for HC was measured by the five-items subscale on HC, moral delegitimization was measured by the four-items subscale on Instrumentalization of Remembrance (e.g., "The Jews exploit the memory of the Holocaust for their own benefit"), and perpetrator suffering was measured by the three-items Generalization of The Victims subscale (e.g., "The Germans also had to suffer a lot during the Second World War"). Finally, collective guilt was measured by means of two items adapted from Study 1. Except for collective narcissism and national identification (which ranged from 1 = *fully disagree* to 7 = *fully agree*), all other items had to be answered on a 5-point Likert-scale anchored at 1 = *fully disagree* to 5 = *fully agree*. For exploratory purposes, we additionally measured RWA, political orientation, and support of refugees.

Results

Descriptive Statistics, Mean Differences, Correlations and Manipulation Check

Descriptive statistics, tests of mean differences (none significant), and correlations are given in Table 2. Significant mean differences in the manipulation check questions confirmed that in the ingroup criticism condition ($M = 2.20$, $SD = 0.83$), the presented opinion about Germany was perceived less favorable than in the praise condition ($M = 4.03$, $SD = 0.94$), $t(371) = 19.98$, $p < .001$, $d = 2.05$. Moreover, participants felt less positive after reading the criticism article ($M = 2.16$, $SD = 0.86$), compared to the praise article ($M = 3.17$, $SD = 0.91$) $t(367) = 10.90$, $p < .001$, $d = 1.24$.

[Table 2 here]

Moderation Analyses on Demand for HC

To test our hypothesis that demand for HC would be positively associated with collective narcissism, even when controlling for genuine national identification and pride, potentially moderated by ingroup praise, we performed a series of hierarchical multiple regression analyses

(Table 3). Collective narcissism, national identification and pride were centered prior to analyses and the condition was dummy-coded (two dummy-coded variables, praise vs criticism, control vs criticism as reference category). In line with our hypotheses, collective narcissism was significantly positively related to HC, even when including national identification and pride (see Model 1). However, contrary to our hypotheses, there were no significant interaction effects with condition (Model 2).

[Table 3 here]

Multiple Mediation Analyses on Collective Guilt

In a first step, we conducted a multiple mediation analysis, specifying collective narcissism as predictor, the defensive mechanisms (demand for HC, moral delegitimization and perpetrator suffering) as mediators and collective guilt as outcome variable (Model 1). In a second step, we added national identification, national pride (both centered) and the two dummy-coded condition variables (criticism as reference category) as predictors (Model 2). In a third step, we additionally included the two-way interactions of ingroup positivity measures and conditions as predictors (Model 3). Yet, none of the interaction terms were significantly related to any of the defensive mechanisms or collective guilt (see SOM C for Model 3 with all two-way interactions).

In Model 1 and 2 (Table 4, Figure 1), collective narcissism was positively associated with all three defensive mechanisms, but only via demand for HC indirectly related to collective guilt (significant indirect and total indirect effects). Significant total effects in absence of significant direct effects of collective narcissism in both models supported the assumption that individuals high in collective narcissism express less collective guilt, fully mediated via demand for HC. Model 2 furthermore revealed that in contrast to collective narcissism, national pride was negatively associated with demand for HC and moral delegitimization as well as indirectly positively associated with guilt via demand for HC. Yet, the focal total effect of national pride

was not significant, suggesting that national pride was overall not substantially related to guilt. Finally, the praise condition reduced moral delegitimization compared to the control condition. Multicollinearity diagnostics did not identify any problems in any of the models: All variance inflation factors (VIFs) were below 2.94 and all Tolerances were above .35.

[Table 4 and Figure 1 here]

Additional Analyses in SOM

The presented analyses differ slightly from the pre-registered analyses that proposed to calculate the moderation models without the control group and to use a combined index of guilt and reparation intentions as the main outcome variable. However, during the review process we reached the conclusion that including the control group and focusing on guilt only (see SOM D for factor analyses) would be conceptually clearer. The pre-registered moderation (SOM E.1) and mediation models (SOM E.2) did not differ in statistical inferences from the present results.

We also report an additional mediation model excluding national pride (to control for suppressor effects, SOM F.1), as well as an extended mediation model accounting for age, gender, RWA and political orientation (to rule out the possibility that the association between collective narcissism and demanding HC was spurious and driven merely by an overlap with political ideology, SOM F.2). In both of these control models, the association between collective narcissism and collective guilt via demand for HC remained stable. Finally, we tested our mediation model with regard to prosociality toward a group not related to the German perpetrator past (i.e., refugees; SOM G).

Discussion

Study 2 replicated our previous finding that individuals with an overly positive, but fragile view of their national group (i.e., collective narcissism) were more prone to demand HC and reported less collective guilt. Moreover, in line with our predictions, collective narcissism

was indirectly related to collective guilt only via demanding HC but not via moral delegitimization and perpetrator suffering (e.g., Bandura, 1999; Noor et al., 2012; Opatow, 1990). These results provide initial evidence for the particular importance of claims for HC, compared to certain other prominent strategies of historical defensiveness (Bilewicz, 2016), for the reduction of collective guilt among individuals high in collective narcissism.

While collective narcissism was positively associated with claims for HC, the association between national identification and demand for HC was non-significant, and the relation between national pride and HC was even significantly negative. Furthermore, national pride was indirectly positively associated with collective guilt when accounting for the shared variance with collective narcissism. The latter result is consistent with literature indicating that previously positive associations between secure ingroup positivity and defensive responses can reverse when controlling for the defensive component captured by collective narcissism (Dyduch-Hazar et al., 2019; Golec de Zavala et al., 2013a). However, the focal total effect of national pride on collective guilt was not significant, suggesting that national pride is less relevant than collective narcissism in explaining collective guilt for the ingroup's perpetrator past.

Contrary to our expectations and deviating from findings in the area of outgroup defensiveness (Golec de Zavala et al, 2013b), ingroup praise (vs. criticism) could not attenuate the defensive potential of collective narcissism. Instead, praise led to less moral delegitimization compared to criticism, suggesting that criticism of the ingroup's dealing with historical transgressions may elicit the specific defensive reaction of morally downgrading the victims of those transgressions. Unexpectedly, this effect was not stronger among individuals high in collective narcissism.

One explanation for the lack of an interaction effect could be that the manipulation was not strong enough to induce sufficient ingroup praise. Although the manipulation check was significant, it is important to note that both conditions were related to Germany's dealing with

the Nazi past. Thus, both made the Nazi crimes salient, or in other words, contained an implicit ingroup critique. Since individuals high in collective narcissism are constantly looking for signs of insufficient appreciation of the ingroup (Golec de Zavala & Schatz, 2012), they might have been sensitive to this criticism which ultimately may have collapsed a potential buffering effect of praise. Moreover, the confound of the manipulation with the topic that HC is about, namely the German perpetrator past, may also have been responsible for the insignificant moderation effect. Hence, the next study introduced a praise condition that was not connected to the Nazi past.

Study 3

Study 3 aimed at replicating the previous findings and to extend them beyond self-reported collective guilt. Therefore, we introduced a real-world behavioral measure of willingness to compensate Holocaust victims: donations to a social organization that supports Holocaust survivors and their families. A resource allocation task represents a situation that people might encounter outside a laboratory setting, thus enhancing the ecological validity of the present research. Additionally, Study 3 introduced a more powerful manipulation of ingroup praise, independent of the context of the Nazi era. Specifically, the manipulation was based on the *Best Countries Report* of 2016 (Wharton University of Pennsylvania, 2016), which praised Germany on numerous social and political levels, including Germany's economic success and mediating role in international conflicts. Replicating Study 2, we included national identification and national pride in a complementary fashion to collective narcissism, expecting that only collective narcissism would significantly interact with the experimental condition. Similar to Study 2, we also controlled for potential mediating effects of moral delegitimization and perpetrator suffering.

Method

Participants

Based on the same power considerations as in Study 2, we needed 380 participants to detect an interaction effect of condition and collective narcissism. Since we knew from Study 2 that we could expect a considerable dropout due to our exclusion criteria, we aimed for a total of $N = 430$ participants to rebalance for the dropout. A sample of 438 participants was recruited for a study on political issues in Germany via diverse social media platforms and a website hosting links to unpaid online surveys. The participants had the chance to take part in a raffle of 10 online vouchers worth 20 euros. According to our pre-registered exclusion criteria, 34 participants were excluded from analyses ($n = 4$ stated to have clicked at random; $n = 6$ excluded due to extremely fast termination with relative speed index > 2.0 , Leiner, 2019; $n = 2$ were Jewish; $n = 22$ indicated that they speak any other language than German at home or that they were refugees). This resulted in a final sample of 404 participants with a mean age of $M = 34.61$ years ($SD = 14.88$, age ranging from 17 to 99). There were more respondents who identified as women (64%) than as men (35%) or diverse individuals (1%).

Procedure and Materials

First, collective narcissism, national identification, and national pride were assessed. Subsequently, participants were randomly assigned to one of the three experimental conditions. The experimental conditions based on slightly modified real newspaper articles about the *Best Countries Reports 2016* and *2017*, conducted by the News & World Report, BAV Consulting and the University of Pennsylvania (see Wharton University of Pennsylvania, 2016, 2017). These reports evaluated 60 to 80 countries across a wide range of criteria including global power, economic influence, and quality of life. While in 2016, Germany was ranked as “the best country in the world”, in 2017 Germany dropped to place 4. Participants in the *praise* condition ($n = 130$) thus read an article on the Best Countries Report of 2016 which highlighted Germany’s

global magnificence. Participants in the *criticism* condition ($n = 134$) read an article on the report of 2017 which focused on Germany's loss of power and global reputation. In the control condition ($n = 140$), participants read a neutral report about the living of an indigenous people (full articles are available on our OSF project site). After reading the article and answering the manipulation check (same as in Study 2 but this time feelings were measured also in the control condition), all participants completed items on the three defensive mechanisms, demand for HC, perpetrator suffering and moral delegitimization. To hide the purpose of the study, these were presented in a randomized order, mixed with several filler items relating to the social shaping of the future (e.g., "Innovations play a major role in the future of Germany").

Afterwards participants were informed that before the last demographic questions were asked, they would have the opportunity to participate in a raffle (10 times 20 euros), of which an amount could be donated to one of four social organizations (all four currently active in Germany). The goals and activities of each of the following four organizations were presented in short texts in randomized order: *Aktion Sühnezeichen Friedensdienste* (supports Holocaust victims and their families as well as promotes education on the Shoah), *Bund der Kriegsblinden Deutschlands e.V.* (supports German people blinded by war), *Bundesvereinigung Lebenshilfe e.V.* (supports mentally disabled people in Germany), *Seelefon* (offers culturally sensitive advice and support for refugees). Participants were asked to indicate explicitly how much money they want to donate to each of the four organizations and how much money they would like to keep for themselves in case they win, each on a scale from 0 to 20 euros. Donations were encouraged by informing the participants that each euro donated will be doubled by the institution of the investigators. The percentage share of donations to the social organization that supports Holocaust survivors was used as the main dependent variable. Finally, participants were directed to the sociodemographic section. This section also included the items on collective guilt.

The two manipulation check items, measures of collective narcissism, national identification, pride, demand for HC, moral delegitimization, perpetrator suffering, and collective guilt were the same as that used in Study 2. All items ranged from 1 (*strongly disagree*) to 7 (*strongly agree*). For exploratory purposes, we additionally assessed RWA, political orientation, SDO, national attachment, glorification, as well as anticipated emotional distress and intentions to get in contact with Jewish or Muslim people.

Results

Descriptive Statistics, Mean Differences, Correlations and Manipulation Check

Descriptive statistics, mean differences and intercorrelations among study variables are given in Table 5. The manipulation check indicated that in the criticism condition ($M = 3.77$, $SD = 1.04$) the presented opinion about Germany was rated significantly less positive than in the praise condition ($M = 6.43$, $SD = 0.95$), $t(261) = 21.75$, $p < .001$, $d = 2.67$. In terms of feelings that the article triggered, an ANOVA and Bonferroni-Holm corrected post-hoc tests indicated that the criticism article elicited significantly fewer positive feelings ($M = 3.90$, $SD = 0.86$) than the praise article ($M = 4.58$, $SD = 1.11$), $F(2,401) = 43.16$, $p < .001$, $t(242) = 5.50$, $p < .001$, $d = 0.68$, and the control article ($M = 5.01$, $SD = 1.00$), $t(269) = 9.87$, $p < .001$, $d = 1.19$. The control article also triggered significantly more positive feelings than the praise article, $t(260) = 3.38$, $p < .001$, $d = 0.41$.

[Table 5 here]

Moderation Analyses on Demand for HC

Similar to Study 2, we performed a series of hierarchical multiple regression analyses (Table 6). Out of the three ingroup positivity measures, collective narcissism was the only one significantly positively related to HC (see Model 1). However, contrary to our predictions, there were no significant interaction effects with condition (Model 2).

[Table 6 here]

Multiple Mediation Analyses on Donations in Support of Holocaust Victims

In a first step, we conducted a multiple mediation analysis of collective narcissism on percentage of money donated in support of Holocaust victims via all three defensive mechanisms (Model 1). In a second step, we added the two other types of ingroup positivity (centered) and the dummy-coded condition variables (criticism as reference category) as further predictors (Model 2). In line with the pre-registration, participants who kept the entire 20 euros for themselves were not included in the corresponding analyses, which resulted in a sample of $N = 321$. A third model additionally included the two-way interactions of experimental conditions and the three types of ingroup positivity as predictors (Model 3). However, none of the interactions were significantly related to any of the defensive mechanisms or donations (see SOM H for Model 3).

In Models 1 and 2 (Table 7, Figure 2), collective narcissism was positively related to the three defensive mechanisms. Yet, none of the three defensive mechanisms were significantly related to donations. Thus, while all three mechanisms were significantly negatively associated with donations in support of Holocaust victims when looking at zero-order correlations (see Table 5), none of them remained significantly associated with donations when controlling for their shared variance in the multiple mediation model. Accordingly, there were no significant focal indirect effects. However, the total indirect effect via all three defensive mechanisms and the total effect of collective narcissism were significant in both models, while the direct effect was not, suggesting that collective narcissism was related to donations fully mediated via all three defensive mechanisms.

Model 2 further revealed that the praise condition significantly enhanced claims for HC and moral delegitimization of the victims compared to the criticism condition, while the control condition significantly enhanced claims for HC compared to the criticism condition. Yet, none of the two conditions had indirect or total indirect effects on donations. However, the control

condition had a significant negative direct and total effect on donations, suggesting that the control condition reduced donations, independent of the three defensive mechanisms.

[Table 7 and Figure 2 here]

Multiple Mediation Analyses on Collective Guilt

Replicating Study 2, we conducted a multiple mediation analysis specifying collective guilt as outcome variable (Table 8, Figure 3). Whether controlling for national identification and pride (Model 2) or not (Model 1), collective narcissism was positively associated with all three defensive mechanisms but indirectly related to collective guilt fully mediated only via endorsing HC. In contrast, national pride was directly positively related to collective guilt. Yet, the focal total effect of national pride on collective guilt was not significant.

Model 2 further indicated a direct negative effect of the control condition on collective guilt, and a positive relationship between demand for HC and the praise as well as the control condition. Significant focal indirect, total indirect and total effects of both conditions suggested that the relationship between the praise condition and collective guilt was fully mediated via HC, whereas the relationship between the control condition and guilt was partially mediated via HC. Adding the two-way interactions of ingroup positivity measures and condition (Model 3), moreover revealed a significant interaction of collective narcissism and control condition on HC, $B(SE) = 0.21(0.10)$, $\beta = 0.23$, 95% CI [0.01, 0.40], $p = .039$, with a stronger association between collective narcissism and HC in the control condition, $B(SE) = 0.64(0.06)$, $\beta = 0.70$, 95% CI [0.40, 0.87], $p < .001$, than in the criticism condition, $B(SE) = 0.47(0.05)$, $\beta = 0.52$, 95% CI [0.38, 0.56], $p < .001$ (only significant interaction effect, see SOM I for full Model 3). This suggests that the praise and control conditions overall elicited more demand for HC than the criticism condition, with particularly strong reinforcement of HC among individuals in the control condition who were high in collective narcissism. However, neither the indirect effect via HC nor the total effect of this interaction term on collective guilt were significant.

Multicollinearity diagnostics did not reveal any problems in any model (all VIFs < 3.37, all Tolerances > 0.30).

[Table 8 and Figure 3 here]

Additional Analyses in SOM

The pre-registered moderation analysis, which did not differ in statistical inferences from the present results, is reported in SOM J. To extend the scope of the present research, we ran an additional mediation analysis on collective guilt specifying ingroup attachment, glorification, RWA, SDO, and political orientation as additional predictors. Results indicated that only collective narcissism but no other type of ingroup positivity (national identification, pride, attachment, and glorification) was significantly related to claims for HC. Yet, the focal total effect of collective narcissism on guilt was reduced to non-significant in this extended model (SOM K). We moreover calculated additional chain models indicating that demanding HC fully mediated the association between the other two defensive strategies and collective guilt (SOM L). Finally, we explored the relationships between collective narcissism, and two additional variables that were found to be associated with collective guilt, namely anticipated emotional distress and contact intentions (Imhoff et al., 2012, see SOM M).

Discussion

Congruent with the results of Study 2, collective narcissism was significantly negatively related to collective guilt, fully mediated via the demand for HC, thereby surpassing two types of rather secure ingroup positivity (genuine national identification and national pride; Cichocka, 2016) and two other prominent defensive mechanisms (perpetrator suffering and moral delegitimization of the victims; Bandura, 1999; Noor et al., 2012; Opatow, 1990). These findings extend previous results on the pronounced defensive motivation in collective narcissism compared to secure types of ingroup positivity (Golec de Zavala et al., 2013a) to the areas of historical defensiveness and collective guilt. Furthermore, they substantiate the previously

scarcely examined particular importance of demanding HC for the reduction of guilt among individuals high in collective narcissism (Imhoff, 2010a).

We also found a significant effect of collective narcissism on reduced donations in support of Holocaust victims. This result is particularly important since it indicates that defensive reactions of individuals high in collective narcissism are reflected in real-world behavior, such as the allocation of donations. However, contrary to our expectations, the indirect association between collective narcissism and donations in support of Holocaust victims was not mediated only via claims for HC, but via all three defensive mechanisms, HC, perpetrator suffering and moral delegitimization. Multicollinearity between the defensive mechanisms might explain the lack of unique indirect effects in presence of a significant total indirect effect (Preacher & Hayes, 2008). Potentially, due to higher overlap in explained variance in monetary donations than in collective guilt between the defensive mechanisms, none of the focal indirect effects was strong enough to be adequately disentangled from the others in the model addressing donations. This could be because real-world behavior (e.g., donations) is a less precise measure of solely one construct (e.g., collective guilt) but may simultaneously measure several different constructs. For instance, rejecting donations to a social organization that supports Holocaust survivors may reflect not only variance in collective guilt, but also a general lack of sympathy for Jewish people or for German people engaged in Holocaust education, thereby perpetuating the confrontation with the image-threatening perpetrator past. These attitudes, in turn, may have been related not only to HC but also to moral delegitimization and perpetrator suffering.

Contrary to our expectations, even extensive ingroup praise could not buffer the association between collective narcissism and demanding HC. Instead, the praise condition reduced collective guilt compared to the criticism condition, fully mediated via demand for HC, and the control condition reduced donations in support of Holocaust victims and collective guilt relative to the criticism condition, the latter partly mediated via demand for HC. Although not

expected in the present study, the finding that criticism decreases demand for HC, with downstream consequences for collective guilt, is consistent with previous research indicating that ingroup criticism can reduce the perceived moral entitlement to blatantly express HC (Kazarovytska et al., 2022). The direct negative effect of the control condition relative to the criticism condition on collective guilt and donations in support of Holocaust victims mirrors previous findings (Gausel et al., 2012) showing that perceived ingroup defect can lead group members to engage in reparative behavior.

General Discussion

The past can act as a heavy weight on a group. It is thus not surprising that members would want to take action to remove this weight and associated feelings of guilt. Across three studies, we showed that some members do so by closing the book on negative ingroup history. In closing the book, there is no denial that past harms were committed but rather a belief that a line should be placed under history. Cumulative evidence was provided to support the previously unexplored hypothesis that collective narcissism is related to higher levels of demand for HC and reduced collective guilt within the context of the Holocaust.

Collective narcissism (Golec de Zavala et al., 2009) was indirectly related to collective guilt via the demand for HC. This indirect association remained significant, even when controlling for potential indirect paths via the two defensive strategies moral delegitimization of the victims (Bandura, 1999; Opatow, 1990) and desire for recognition of the perpetrator ingroup's suffering (Noor et al., 2012; Wohl & Branscombe, 2008). From an emotion regulation perspective (Bilewicz, 2016), one could assume that any defensive strategy that serves to reduce the ingroup's agency for past wrongdoings might reduce collective guilt. However, the uniqueness of the indirect effect between collective narcissism and collective guilt via demanding HC suggests that the need to mitigate collective guilt among individuals high in collective narcissism may be most clearly satisfied by HC. Yet, with respect to more complex

behaviors, such as donating money to support Holocaust victims, the unique indirect path via HC faded but spread to all three defensive mechanisms. We assume here a multicollinearity effect of the three defensive mechanisms, rooted in the assumption that donating money to Holocaust survivors has more complex motives than collective guilt. This assumption is also substantiated by the finding that collective narcissism explained more variance in collective guilt (medium effect sizes) than in donation behavior (small effect size according to the conventions of Cohen, 1988). Accordingly, high collective narcissism seems to be clearer associated with a reduction of the aversive emotional experience of collective guilt (Branscombe et al., 1999; Doosje et al., 1998; Imhoff et al., 2013) than with donation behavior.

Across all three studies, demand for HC was particularly strong among individuals high in collective narcissism (large effect sizes; Cohen, 1988). The addition of further measures of ingroup positivity as predictors contributed only marginally to an increase in explained variance in demand for HC. While the association between genuine national identification and HC was reduced to non-significant when partialling out the common variance with collective narcissism and national pride (Studies 2 and 3), the association between national pride and claims for HC even turned significantly negative (Study 2). The latter findings fit prior research that pulled apart the opposite effects of secure and narcissistic ingroup positivity on ingroup image defense (Golec de Zavala et al., 2013a), including the opposite effects of secure ingroup satisfaction and collective narcissism on defensiveness toward a confrontation with the ingroup's historical transgressions (Dyduch-Hazar et al., 2019). We obtained such opposing effects only for national pride but not for national identification, which fits previous research indicating that the interplay of mutual suppression with collective narcissism on defensive responses may be more pronounced for certain types of secure ingroup positivity than for others (see e.g., Marchlewska et al., 2020 for divergent suppression effects of group-based self-definition and self-investment). Consistent with the assumption of Golec de Zavala and colleagues (2013a), we reason that

different measures of secure ingroup positivity capture different aspects of the overlap with narcissistic ingroup positivity, which can lead to a reduction of defensive reactions or enhancement of collective guilt for some types of secure ingroup positivity and null relations to defensive responses and guilt for other types.

Our findings further extend the research on ingroup image defense to the area of attitudes toward the ingroup's harmful past. Prior research indicated that individuals high in collective narcissism discredit movies and books pointing to past wrongdoings of the ingroup (Dyduch-Hazar et al., 2019) just as they discredit other sources of ingroup criticism (Golec de Zavala et al., 2013b). The present research indicates that individuals high in collective narcissism also tend to distance from the negative past itself by denying its relevance to the present and the legitimacy to further engage with it as well as express less collective guilt. These results show a parallel to individual narcissists, who are also prone to distance themselves from self-threatening memories (Marchlewska & Cichocka, 2017). Specific to the German sample, the present research is among the first to provide evidence for the longstanding assumption that demanding HC is related to a narcissistic idealization of the German group – especially “among those who cannot cope with national guilt and therefore seek to defend their main source of collective narcissistic gratification” (Rensmann, 2017, p. 23).

We found no support for a mitigation of the defensive reactions in individuals high in collective narcissism by experimentally inserting praise of the ingroup's achievements in dealing with past harmdoing (Study 2) or praise of the ingroup on a global scale (Study 3). However, in Study 3, both the ingroup praise and control condition increased demand for HC and reduced collective guilt compared to the criticism condition, with the control condition also increasing actual donations in support of Holocaust victims. These findings correspond with prior research indicating a prosocial effect of ingroup criticism (Gausel et al., 2012). The finding that this group

difference was found only in Study 3, but not in Study 2, suggests that quite extensive ingroup critique may be required to cause effects on HC, collective guilt and donation behavior.

While the lack of an interaction of collective narcissism and ingroup praise deviates from prior findings showing that ingroup praise can buffer the defensiveness of individuals high in collective narcissism toward criticizing outgroups (Golec de Zavala et al., 2009, 2013b), it is in line with the findings of Čehajić-Clancy and colleagues (2011), who also failed to increase collective guilt and support for reparations of intergroup harm done by affirming the ingroup. The authors reasoned that reinforcing a positive image of the ingroup through affirmation may cause the ingroup's misbehavior to be perceived as even more self-threatening, which may make endorsement of collective guilt or reparative action more difficult.

Another explanation for the deviation from previous findings in the area of collective narcissistic outgroup defensiveness (Golec de Zavala et al., 2013b) could be the difference in the context of the criticism (different vs. same group context as a source of the criticism) and the extent to which the defensive response can reduce the threatening effect of the criticism. Discrediting an ingroup-criticizing outgroup may call into question the credibility of that criticism but asserting HC may not mitigate criticism of current ingroup dynamics, such as a loss of global reputation. Future research might test such moderating effects of the criticism context as well as the content fit of criticism and defensive response.

Finally, individuals high in collective narcissism are concerned, on the one hand, with upholding a positive image of their group for the outside world (Cisłak et al., 2021a). On the other hand, they might have (unacknowledged) doubts about the ingroup's greatness (Golec de Zavala et al., 2009) which may motivate them to defend a positive image of the ingroup for themselves. A history marked by tremendous intergroup transgressions might be particularly threatening (Branscombe et al., 1999) – not only to the outside image but also to the own shaky

beliefs about the ingroup's greatness. Potentially, the threat resulting from reminders of these transgressions is thus too strong to be offset by ingroup praise.

Limitations and Directions for Further Research

One of the major limitations of the present studies is that the results are purely correlational, as the defensive response in collective narcissists could not be manipulated by the experimental conditions. Thus, the emotion-regulatory function of demand for HC still has to be tested in experimental or longitudinal studies. A second central limitation of our research is that it was conducted only in the context of the German Nazi past. An interesting avenue for future studies could be to identify whether the striking connection between demanding HC and collective guilt can be replicated in other contexts of historical perpetration. For instance, Jung (2009) argued that the demand to draw a line under the past -and thus remove any accountability for past violations against Indigenous peoples- represents one of the main drivers of the Canadian government's use of transitional justice measures. Efforts to achieve closure have also been identified with regard to the Northern Ireland conflict (Brewer & Hayes, 2015), the history of slavery and colonialism in the United States and Britain (Adi, 2012; Neiman, 2019), the crimes committed during the legacy of the Soviet regime (Khazanov & Payne, 2008), or the war crimes of Imperial Japan (Liu & Atsumi, 2008). Although in these contexts, the demand for HC has been *discussed* as an important strategy for maintaining ingroup positivity and delimiting collective guilt, little research has been devoted to *empirically examine* this assumption.

Another limitation concerns our measure of secure national identification, which tapped mainly into the *solidarity* aspect referring to the belongingness and similarity with ingroup members. Accordingly, other components of identification, such as centrality and satisfaction (Leach et al., 2008) were not captured. Thus, our measurement might not represent national identification in its entirety. However, it should be noted that these three components of self-

investment are highly intercorrelated and the concept of ingroup identification appeared to be so homogeneous that it could even be measured by a single item (Postmes et al., 2013).

Future research could further seek to analyze in more detail the different components of HC. It is conceivable that demanding HC includes not only defensive components (i.e., the desire to close the chapter on a threatening past) but also rather genuine components (i.e., a general perception that the past is not relevant for the present). Research on past time perspective indicates that individuals may vary in the extent they prefer to engage with the past (Karniol & Ross, 1996). This idea might be transferred to the group level. Yet, Bilewicz (2016) identified the focus on presence and future as another emotion-regulation strategy within the framework of historical defensiveness. Thus, it seems particularly relevant to empirically differentiate between an authentic focus on the ingroup's presence and simply another -potentially socially acceptable- expression of defensiveness against the engagement with the ingroup's historical wrongdoings.

Finally, future research might examine how the degree to which people endorse HC is related to further intergroup and ingroup dynamics. In fact, demanding HC has been identified as a core element of modern antisemitism (Imhoff, 2010b), which is intimately associated with a conspiracy mentality (Imhoff & Bruder, 2014) that is also related to collective narcissism (e.g., Cichocka et al., 2015; Cislak et al., 2021b). In this vein, the officially promoted relevance of dealing with the Nazi past, which is opposed to a HC, could be perceived as driven by hostile forces (or even the victim group itself; Imhoff, 2020), aiming at undermining the ingroups self-confidence. Further research may thus strive to analyze the interplay of these ingroup and intergroup attitudes and demand for HC.

Conclusion

Already in 1959, Adorno suspected that the Germans' efforts of "coming to terms with the past" were not intended to actually face the atrocities of the past but to "close the books on the past and, if possible, even remove it from memory" (Adorno, 1999; p. 89). More than 60 years

later, the debate about a *Schlussstrich* has not lost any of its explosiveness. It is not the factuality of the era of National Socialism that is called into question, but the relevance of a social and political confrontation with this past in present time. The present research sheds light on relevant ingroup-related attitudes associated with the demand for a HC. When achieved, collective guilt for harms committed by the ingroup can be circumvented. Group members who do not accept collective guilt for past acts are unlikely to attempt to repair wrongs committed – a significant barrier to pro-social intergroup relations.

Footnotes

¹ For theoretical clarification, it is important to emphasize that collective narcissistic ingroup positivity is not unconditional but individuals high in collective narcissism may also have negative attitudes toward ingroup members, for example, toward those who criticize the ingroup (e.g., Golec de Zavala & Lantos, 2020).

² We conducted another study (Study S1) aiming at disentangling the effects of collective narcissism, ingroup attachment and glorification (Roccas et al., 2006). Indeed, only collective narcissism but none of the other two ingroup positivity measures were indirectly via HC associated with collective guilt. However, the total effect of collective narcissism on collective guilt was not significant, potentially due to a suppressor effect caused by attachment and glorification (see SOM B for details).

Tables

Table 1

Results of a Simple Mediation Analysis on Collective Guilt in Study 1

Predictor	Demand for HC		Collective Guilt	
	<i>B(SE)</i>	95% CI ^a [<i>LL</i> , <i>UL</i>]	<i>B(SE)</i>	95% CI ^a [<i>LL</i> , <i>UL</i>]
Collective Narcissism	0.50 (0.04)***	[0.42, 0.58]	-0.07 (0.08)	[-0.23, 0.10]
Demand for HC			-0.34 (0.06)***	[-0.46, -0.22]
Indirect Effect via Demand for HC			-0.17 (0.04)***	[-0.24, -0.11]
Total Effect			-0.18 (0.04)***	[-0.26, -0.10]

Note. *N* = 384; CI = confidence interval; *LL* = lower limit; *UL* = upper limit; $R^2 = .28$ for demand for HC; $R^2 = .12$ for collective guilt.

^aFor indirect and total effects the bootstrapped 95% confidence intervals are reported (5000 bootstrapping resamples).

* $p < .05$. ** $p < .01$. *** $p < .001$

Condition: Control ^a							-1.50 (0.48)**	[-2.47, -0.59]

Note. $N = 404$; CI = confidence interval; *LL* = lower limit; *UL* = upper limit; $R^2_{\text{Model 1}} = .35$, $\Delta R^2_{\text{Model 2}} = .02$ for demand for HC; $R^2_{\text{Model 1}} = .36$,

$\Delta R^2_{\text{Model 2}} = .01$ for perpetrator suffering; $R^2_{\text{Model 1}} = .30$, $\Delta R^2_{\text{Model 2}} = .01$ for moral delegitimization; $R^2_{\text{Model 1}} = .15$, $\Delta R^2_{\text{Model 2}} = .02$ for collective guilt.

^aFor indirect and total effects the bootstrapped 95% confidence intervals are reported (5000 bootstrapping resamples).

* $p < .05$. ** $p < .01$. *** $p < .001$.

Figure Titles and Legends

Figure 1

Significant Standardized Path Coefficients (Completely Standardized Solution) of Multiple Mediation Model 2 on Collective Guilt in Study 2

Note. $N = 595$.

* $p < .05$. ** $p < .01$. *** $p < .001$.

Figure 2

Significant Standardized Path Coefficients (Completely Standardized Solution) of Multiple Mediation Model 2 on Donations in Support of Holocaust Victims in Study 3

Note. $N = 321$.

* $p < .05$. ** $p < .01$. *** $p < .001$.

Figure 3

Significant Standardized Path Coefficients (Completely Standardized Solution) of Multiple Mediation Model 2 on Collective Guilt in Study 3

Note. $N = 404$.

* $p < .05$. ** $p < .01$. *** $p < .001$.
